1. Introduction

Southern Ocean ecosystems have been changing since the near extirpation of seals in the 1800s and the overexploitation of many whale species and benthic finfish in the mid-20th century. Since the late 1960s, significant changes to Southern Ocean habitats, probably resulting from the depletion of ozone over the Antarctic, have been observed including increased westerly winds (Turner et al. 2009b) and a movement south of their location indicated by the Southern Annular Mode (Turner et al. 2009a), the extent and timing of sea ice advance and retreat, (although varying greatly from positive to negative regionally (Stammerjohn et al. 2008, Turner et al. 2009a); abrupt loss of ice shelves (Cook et al. 2005, Cook et al. 2010); freshening of Antarctic Bottom Water and surface waters near the continent, a southward shift in the Antarctic Circumpolar Current fronts, along with a changed eddy field (Meredith et al. 2006, Sallée et al. 2010, Sokolov et al. 2009). Increased CO2 in the atmosphere has also led to a decrease in ocean pH (Turner et al. 2009a). The Southern Ocean is expected to substantially change in the coming decades as a result of climate change and ocean acidification (Turner et al. 2009a).

In recent decades, changes in biota and the potential role of change in habitats have been identified (e.g. the role of sea ice, Massom et al. 2010) but the actual mechanisms of change remain poorly understood for many components of the ecosystem (Constable et al. submitted). The projections for change in the structure and function of Antarctic and Southern Ocean ecosystems in response to climate change and recovery of marine mammals are regionally specific due to regional differences in the manifestations of climate change (Constable et al. submitted). For example, a switch from a krill-based food web to a copepod- and fish-based food web in times of low krill abundance (Waluda et al. 2010, Murphy et al. 2012c) suggests that the latter may become more common in the future in the south Atlantic (Shreeve et al. 2012, Trathan et al. 2012). The projections for Antarctic krill to the north is ambiguous, as factors that could impact directly on krill vary regionally, and because they are able to adapt physiologically and behaviourally (Schmidt et al. 2011). New research also shows that larval krill survival may be negatively affected by increasing ocean acidity (Kawaguchi et al. 2011), adding further complexity to these assessments.

Some key trends in distribution and abundance of bird populations (penguins and flying birds) have been linked to recent change (e.g. Barbraud et al. 2009, Trathan et al. 2009, Jenouvrier et al. 2012). The challenge of identifying changes in ecosystem productivity and dynamics than by changes in temperature (Harley et al. 2006). However, the ecological pathways of impact on marine mammals and birds may be difficult to determine because higher predator populations are less sensitive to small-scale spatial and temporal variability of lower trophic levels, such as the contrasting changes in Adélie and other penguin populations (Trivelpiece et al. 2011, Nicol et al. 2012, Smith Jr. et al. 2012).

2. Why good estimates of change are needed

Despite the historical changes to the ecosystem, the Southern Ocean remains the easiest region to separate the ecosystem impacts of climate change and ocean acidification from direct anthropogenic effects — many other regions have continuing and confounding effects of pollution, catchment and coastal zone modification and fisheries (Constable et al. 2009). A monitoring and assessment programme in the Southern Ocean would play an important role in evaluating and estimating the magnitudes and rates of change in global marine ecosystems, testing predictions from climate model scenarios of the Intergovernmental Panel on Climate Change (IPCC) (IPCC 2001, Meehl et al. 2007) and, thereby, provide a sound basis for signalling future changes in ecosystems in the Southern Ocean and beyond. Identifying changes in ecosystem productivity and dynamics is fundamental to achieving ecologically sustainable Antarctic krill fisheries and the conservation of Antarctic marine life as a whole (Constable et al. 2011, Murphy et al. 2012a, Murphy et al. 2012b).

A great difficulty in interpreting the cause of changes is the absence of integrated measurements of a suite of variables across the range of physical and biological properties of Antarctic and Southern Ocean ecosystems (Murphy et al. 2003, Constable et al. 2009, Rintoul et al. 2011). Moreover, attention needs to be given to estimating how regional differences and intra- and inter-annual variability may impact the use of these indicators for assessing long-term trends in the ecosystems (Constable et al. 2006, 2011). Conversely, the regional differences of climate change impacts on habitats in the Southern Ocean provide opportunities for determining how changes in habitats (positive and negative) will impact on ecosystems as a whole.

Future impacts of climate change on marine ecosystems are being predicted using a combination of expert views and simulation models (Hitz et al. 2004, Sarmiento et al. 2004). Predictions to date have focussed on shifts in distribution and abundance of biological populations in marine systems driven by temperature (Harley et al. 2006). However, both abiotic and biotic changes and responses are expected to be significantly more complex (Melbourne-Thomas et al. 2013). For example, survival and condition of many organisms may be more affected by changes in ocean chemistry or by disruptions to food-web dynamics than by changes in temperature (Harley et al. 2006, Clarke et al. 2007, Constable et al. submitted).

Observations are needed to unambiguously validate the conclusions from modelling and forecasting studies. Such a programme is essential for monitoring how the role of Southern Ocean ecosystems in the Earth System is changing, as well as for appropriately setting both ecosystem-based catch limits for krill and finfish species in the region (SC-CAMLR 2011) and conservation requirements for threatened, endangered or recovering species, such as whales and albatross.

3. The Challenge

The great challenge is to assess the status and trends of Southern Ocean marine ecosystems overall, against which change in ecosystem structure and function can be unambiguously assessed in the future. This challenge includes being able to assess the likelihood of different states in the future. There are three subsidiary questions to this challenge:

1. How should status and trends in those ecosystems be assessed and reported and how will the likelihood of future states be assessed?
2. What are the gaps in knowledge that are required to be able to undertake these assessments?
   a. What is the current status of Antarctic and Southern Ocean ecosystems overall?
   b. What are the critical processes, mechanisms and feedbacks that directly influence the population responses of biota to change in their habitats?
3. What observations need to be taken that will indicate a change in state of those ecosystems and provide suitable input to, validation or correction of assessments?

4. International Context

A number of current international initiatives provide the means for coordinating this effort. The ability to undertake integrated, circumpolar ecosystem programmes of this kind is demonstrated by past successful programmes such as BIOMASS (EI-Sayed 1994) and, more recently, the International Polar Year (Krupnik et al. 2011). The biogeographic atlas forms an important milestone in helping deliver what is needed to estimate change in Southern Ocean ecosystems. The current initiatives are outlined here.

4.1. Integrating Climate and Ecosystem Dynamics in the Southern Ocean (ICED)

ICED (http://www.iced.ac.uk) is an international programme that aims to determine the major controls on the dynamics of Southern Ocean ecosystems and the potential for feedbacks as part of the Earth System (Murphy et al. 2008). It is associated with the Scientific Committee on Antarctic Research (SCAR), the Scientific Committee on Oceanic Research (SCOR) and other international programmes. It is part of the International Geosphere-Biosphere Programme’s “Integrated Marine Biogeochemistry and Ecosystem Research” project (IGBP IMBER).

ICED has three main scientific objectives, which are (i) to understand the structure and dynamics of ecosystems in the Southern Ocean and how they are affected by, and feedback to, climate processes, (ii) to understand how ecosystem structure and dynamics interact with biogeochemical cycles in the Southern Ocean, and (iii) to determine how ecosystem structure and dynamics should be incorporated into management approaches for sustainable exploitation of living resources in the Southern Ocean. Its core activity areas will directly contribute to assessing status and trends of Southern Ocean ecosystems and providing a capability for assessing the likelihood of future states. These core activities include the development of ecosystem models, synthesis of historical datasets and the development and coordination of fieldwork.

ICED has a project, the Southern Ocean Sentinel, hereafter termed ‘the Sentinel’, which will utilise the models and field activities in an ongoing integrated programme to assess status, trends and likelihood of future states of Southern Ocean ecosystems as a whole. It has close synergies with other international initiatives within the Southern Ocean science community, as well as the broader Earth System community.
ICED is closely linked to another IMBER programme, Climate Impacts on Oceanic Top Predators (CLIO TOP), particularly in relation to its work on making CLIO TOP the general objective of CLIO TOP (http://www.imber.info/index.php/Science-Regional-Programmes/CLIO TOP) is to organise a large-scale worldwide comparative effort aimed at elucidating the key processes involved in the impact of both climate variability (at various scales) and fishing on the structure and function of open ocean ecosystems and their top predator species. The ultimate objective is the development of a reliable predictive capability for the dynamics of top predator populations and oceanic ecosystems that combines both fishing and climate (i.e. environmental) effects. CLIO TOP is in its second phase with an emphasis on developing scenarios of the evolution of oceanic ecosystems under anthropogenic and natural forcings in the 21st century (Hobday et al. 2013).

4.2. Southern Ocean Observing System (SOOS)

SOOS (http://www.soos.aq) was established to better coordinate routine observing of the Southern Ocean in order to improve our ability to detect and interpret Southern Ocean change across a range of variables and disciplines (Rintoul et al. 2011). It has associations with all international programmes undertaking scientific research in the Southern Ocean. SOOS has six overarching themes in its strategy: (1) the role of the Southern Ocean in the planet’s heat and freshwater balance, (2) the stability of the Southern Ocean overturning circulation, (3) the role of the ocean in the stability of the Antarctic ice sheets and their contributions to sea level rise, (4) the future and consequences of Southern Ocean carbon uptake, (5) the future of Antarctic sea ice, and (6) the impacts of global change on Southern Ocean ecosystems. The sixth theme is complementary to ICED Southern Ocean Sentinel and will be important in observing trends in Southern Ocean ecosystems.

4.3. Scientific Committee on Antarctic Research (SCAR) programmes

SCAR (http://www.scar.org) has a number of programs contributing to understanding change in the Southern Ocean.

The SCAR Life Sciences programme helps coordinate priorities for Antarctic research. These priorities have generally centred on understanding the patterns of biodiversity in Antarctica and the Southern Ocean, and the drivers of change in structure and dynamics of ecosystems. Recently, two programmes have been adopted to further this work. The State of Antarctic Ecosystems (AntEco) programme aims to explain the biodiversity of Antarctica, how it evolved/arrived in the region, its ecology and threats to its persistence in the region. The Antarctic Thresholds — Ecosystem Resilience and Adaptation (Ant-Era) programme aims to determine the biophysical thresholds of Antarctic ecosystems and to define the thresholds for biota along with their resistance and resilience to change.

SCAR also has a Southern Ocean Continuous Plankton Recorder Survey (SO-CPR), which was established in 1991 to map the spatio-temporal variation in biodiversity, distribution and abundance of plankton (Hosie et al. 2003). It is a key component of the Southern Ocean Observing System, and is a founding contribution to the Global Alliance of CPR Surveys (GACS, www.globalcpr.org), which allows Southern Ocean observations to be placed in a global context.

4.4. Scientific Committee for the Conservation of Antarctic Marine Living Resources (SC-CAMLR)

SC-CAMLR (http://www.ccamlr.org/en/science/science) provides scientific advice to the Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR; Constable et al. 2000). As part of its remit, it coordinates the CCAMLR Ecosystem Monitoring Program (CEMP; Agnew 1997). At present, CEMP has a primary focus on monitoring ecosystem components that affect or are affected by Antarctic krill, Euphausia superba. This is because krill is the focus of the largest fishery in the Southern Ocean, and therefore, changes in krill abundance/distribution could impact on most marine mammal and bird species in the region because of their dependence on Antarctic krill as prey.

5. Approaches

In its simplest form, the status of Antarctic and Southern Ocean marine ecosystems is determined by the relative abundances of the different taxa, taking account of different habitats, trophic levels, and seasonal variability. Trends in populations need to be described in relation to sources of interannual variability, so that differences over time can be attributed to random events, or systematic changes (physical or biological) that may be cyclical or longer term trends. Relating observations to the true state of an ecosystem is a major challenge. This is particularly true for analyses across many taxa, habitats and the varying temporal and spatial scales at which different components of the ecosystem operate. Techniques are usually employed so that not all taxa in an ecosystem need to be observed in order to assess biodiversity or the relative abundance of taxa at different trophic levels. However, some understanding is needed of how these summary observations relate to the overall status of taxa in the ecosystem.

Beyond the empirical data and assessments of status and trends, we also need an understanding of the key ecological processes (or “drivers,” or “forcings”) that directly or indirectly cause the ecosystem dynamics. This knowledge enables understanding of the consequences of assessments for the Earth System, and also for achieving management objectives. The combination of knowledge on status, trends and processes, along with natural variability, enables the development of dynamic models of the ecosystem. These models can then be used to project from the current state to explore possible future states under different scenarios and therefore enable assessments of the likelihood that those states might arise in the future. This process can take account of historical perturbations, such as whaling and sealing, in assessing the likelihood of future states. For example, knowledge of the present status and ecology of whales provides the basis for determining the future trajectory of whales and their potential to directly and indirectly impact on other parts of the ecosystem.

5.1. Current status

Knowledge on the current state of Southern Ocean ecosystems is mostly derived from integrated ecosystem studies on the Antarctic Peninsula and South Georgia, along with expert syntheses across disparate data sets for other regions (see this Volume, Rogers et al. 2012; Constable et al. submitted). This can be extended to other regions by applying the state of krill from the CCAMLR (2000) survey in the Atlantic Sector (Watkins et al. 2004), and the BROKE (1996; Nicol et al. 2000) and BROKE West (2006; Nicol et al. 2010) surveys in East Antarctica. Other work in the past decade also provides a solid foundation for identifying gaps and how to achieve a benchmark for Antarctic and Southern Ocean ecosystems as a whole, including a workshop held jointly between the Scientific Committees of CCAMLR and the International Whaling Commission (SC-CAMLR and SC-IWC 2008) and subsequent publications on primary production (Strutton et al. 2012), zooplankton (Atkinson et al. 2012b), krill (Atkinson et al. 2012a), finfish (Kock et al. 2012), penguins (Ratcliffe et al. 2011) and seals (Southwell et al. 2012).

Impacts on the physical environment of climate change are expected to differ between regions in the Southern Ocean. Synchro-
5.2. Assessing status, trends and likelihood of future states

Methods for summarising the status and trends of ecosystems are in the process of being developed (SC-CAMLR 2008, Shin et al. 2010a) and are now moving beyond the simple mapping of the status of individual taxa to summaries of collective indices, such as size spectra (Jennings et al. 2005, Jennings et al. 2008). Some methods have been developed for combining multiple measures into a single index that can show time trends relative to specific causes of change. To date, this technique requires data over many years to determine which indices will reflect overall status of the ecosystems and provide useful summaries for describing trends that can be used by managers and policy makers (Fulton et al. 2005).

Many models are yet to be developed that can be used to assess the likelihood of future states, although the requirements for the models are now well established (SC-CAMLR 2004, SC-CAMLR and SC-WC 2008, see Murphy et al. 2012a for discussion). Such models will also be useful for informing what observations need to be taken to measure trends in these ecosystems.

5.3. Observing change in Antarctic and Southern Ocean ecosystems

Regular integrated observations of Southern Ocean ecosystems are available on the western margins of the Antarctic Peninsula and from the Scotia arc. Land-based activities are available in other regions as part of the CCAMLR CEMP, or as regular monitoring activities such as at Kerguelen and Crozet Islands (e.g. Barbraud et al. 2012). Regular ship-based activities are also available (e.g., the Continuous Plankton Recorder Survey (Hosie et al. 2003); but these are mostly opportunistic and are not necessarily integrated with land-based and ship-based activities. Observations of the physical system are generally further advanced than for biology (Rintoul et al. 2011). Improved integration of ecosystem observations along with improved coverage through CEMP, SOOS, and ICED Sentinel will be central to improved assessment of status, trends and ecological processes in Southern Ocean ecosystems, as well as giving greater capacity for validating ecosystem models.

5.4. Critical ecosystem processes

Since the work of the BIOMASS programme in the 1980s (El-Sayed 1994), a number of internationally coordinated programmes have sought to better quantify the critical ecosystem processes in Southern Ocean such as factors affecting primary production (the role of iron) and the relative importance of different trophic pathways, the role of sea ice as habitat for krill and other biota, factors that affect the breeding phenology of marine mammals and birds and differences of availability of prey. These have included Southern Ocean GLOBEC (Hofmann et al. 2011), the Discovery 2010 programme (Tarling et al. 2012), and most recently ICED (Murphy et al. 2008). This work is essential for providing the theoretical and quantitative underpinnings for the development of ecosystem models (Murphy et al. 2012a, Murphy et al. 2012b).

6. General

The IPI has provided a strong stimulus to setting up ongoing observations and assessments of trends and status in the Southern Ocean. Current programs are being expanded to be a more comprehensive and integrated assessment of the ecological status of Southern Ocean ecosystems as a whole, using standard methods for biological monitoring. This will help standardise the relative differences between regions and provide consistent foundation against which future changes will be measured. In this process, critical ecosystem models cannot only support the assessments but will help provide a guide as to what measures need to be taken to indicate overall status of Southern Ocean ecosystems. It is envisaged that existing initiatives and further developmental work over the next decade will build on the programmes already underway for the west Antarctic Peninsula, Scotia Arc and CEMP. This work is expected to result in a fully integrated cost-effective programme to measure status and trends in Southern Ocean marine ecosystems overall that could begin with a benchmarking of these ecosystems around 2020.

The Editorial Team

Claude DE BROYER is a marine biologist at the Royal Belgian Institute of Natural Sciences in Brussels. His research interests cover structural and functional biodiversity and biogeography of crustaceans, and polar and deep sea benthic ecology. Active promoter of CAML and ANDEEP, he is the initiator of the SCAR Marine Biodiversity Information Network (SCAR-MarBIN). He took part to 19 polar expeditions.

Huw GRIFFITHS is a marine biogeographer at the British Antarctic Survey. He created and manages SOMBASE, the Southern Ocean Molluscs Database. His interests include large scale biogeographic and ecological patterns in space and time. His focus is on molluscs, bryozoans, sponges and pycnogonids as model groups to investigate trends at high southern latitudes.

Cédric d’UDEKEM d’ACOZ is a research scientist at the Royal Belgian Institute of Natural Sciences, Brussels. His main research interests are systematics of amphipod crustaceans, especially of polar species and taxonomy of decapod crustaceans. He took part to 2 scientific expeditions to Antarctica on board of the Polestar and to several sampling campaigns in Norway and Svalbard.

Bruno DANIS is an Associate Professor at the Université Libre de Bruxelles, where his research focuses on polar biodiversity. Former coordinator of the camerae project, he is a leading member of several international committees, such as OBIS or the SCAR Expert Group on Antarctic Biodiversity Informatics. He has published papers in various fields, including ecotoxicology, physiology, biodiversity informatics, polar biodiversity, or information science.

Susie GRANT is a marine biogeographer at the British Antarctic Survey. Her work is focused on the design and implementation of marine protected areas, particularly through the use of biogeographic information in systematic conservation planning.

Christoph HELD is a Senior Research Scientist at the Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research, Bremerhaven. He is a specialist in molecular systematics and phylogeny of Antarctic crustaceans, especially isopods.

Falk HUETTMANN is a ‘digital naturalist’ he works on three poles (Arctic, Antarctic and Hindu-Kush Himalaya) and elsewhere (marine, terrestrial and atmospheric). He is based with the University of Alaska-Fairbanks (UAFA) and focuses primarily on effective conservation questions engaging predictions and open access data.

Philipp KOUBBI is professor at the University Pierre et Marie Curie (Paris, France) and a specialist in Antarctic fish ecology and biogeography. He is the Principal Investigator of projects supported by EEC, the French Polar Institute. As a French representative to the CCAMLR Scientific Committee, his main input is on the proposal of Marine Protected Areas. His other field of research is on the ecoregionalisation of the high seas.

Ben RAYMOND is a computational ecologist and exploratory data analyst, working across a variety of Southern Ocean, Antarctic, and wider projects research. His current research interests include system modeling, repurposing and marine protected area selection, risk assessment, animal tracking, seabird ecology, complex systems, and remote sensed data analyses.

Anton VAN DE PUTTE works at the Royal Belgian Institute for Natural Sciences (Brussels, Belgium). He is an expert in the ecology and evolution of Antarctic fish and is currently the Science Officer for the Antarctic Biodiversity Portal www.biodiversity.aq. This portal provides free and open access to Antarctic Marine and terrestrial biodiversity of the Antarctic and the Southern Ocean.

Bruno DAVID is CNRS director of research at the laboratory BIOGEOSCIENCES, University of Burgundy. He develops projects which are dedicated to biodiversity and more specifically on sea urchins. He authored a book and edited an extensive database on Antarctic echinoderms. He is presently President of the scientific council of the Muséum National d’Histoire Naturelle (Paris), and Deputy Director at the CNRS Institute for Ecology and Environment.

Julian GUTT is a marine ecologist at the Alfred Wegener Institute Helmholtz Centre for Polar and Marine Research, Bremerhaven, and professor at the Oldenburg University, Germany. He participated in 13 scientific expeditions to the Antarctic and was twice chief scientist on board Polarstern. He is member of the SCAR committees ACCC and Ant-EFA (as chief officer). Main focus of his work are biodiversity, ecosystem functioning and services, response of marine systems to climate change, non-invasive technologies, and outreach.

Graham HOSIE is Principal Research Scientist in zooplankton ecology at the Antarctic Agricultural Research Centre. He founded the SCAR Southern Ocean Continuous Plankton Recorder Survey and is the Chief Officer of the SCAR Life Sciences Standing Scientific Group. His research interests include the ecology and biogeography of plankton species and communities, notably their response to environmental changes. He has participated in 17 marine science voyages to Antarctica.

Alexandra POST is a marine geoscientist, with expertise in benthic habitat mapping, sedimentology and geomorphological characterisation of the seafloor. She has worked at Geoscience Australia since 2002, with a primary focus on understanding seafloor processes and habitats on the East Antarctic margin. Most recently she has led work to understand the biophysical environment beneath the Amery Ice Shelf, and to characterise the habitats on the George V Shelf and slopes following the successful CANA voyages in that region.

Yan ROPERT COUDERT spent 10 years at the Japanese National Institute of Polar Research, where he graduated as a Doctor in Polar Sciences in 2001. Since 2007, he is a permanent researcher at the CNRS in France and the director of a polar research group. His research examines the ecological responses of Adelie penguins to environmental changes. He is also the secretary of the Expert Group on Birds and Marine Mammals of the IUCN-SCC Committee on Antarctic Research.

THE BIOGEOGRAPHIC ATLAS OF THE SOUTHERN OCEAN

Scope

Biogeographic information is of fundamental importance for discovering marine biodiversity hotspots, detecting and understanding impacts of environmental changes, predicting future distributions, monitoring biodiversity, or supporting conservation and sustainable management strategies.

The recent extensive exploration and assessment of biodiversity by the Census of Antarctic Marine Life (CAML), and the intense compilation and validation efforts of Southern Ocean biogeographic data by the SCAR Marine Biodiversity Information Network (SCAR-MarBIN / OBIS) provided a unique opportunity to assess and synthesise the current knowledge on Southern Ocean biogeography.

The scope of the Biogeographic Atlas of the Southern Ocean is to present a concise synopsis of the present state of knowledge of the distributional patterns of the major benthic and pelagic taxa and of the key communities, in the light of biotic and abiotic factors operating within an evolutionary framework. Each chapter has been written by the most pertinent experts in their field, relying on vastly improved occurrence datasets from recent decades, as well as on new insights provided by molecular and phylogeographic approaches, and new methods of analysis, visualisation, modelling and prediction of biogeographic distributions.

A dynamic online version of the Biogeographic Atlas will be hosted on www.biodiversity.aq.

The Census of Antarctic Marine Life (CAML)

CAML (www.caml.aq) was a 5-year project that aimed at assessing the nature, distribution and abundance of all living organisms of the Southern Ocean. In this time of environmental change, CAML provided a comprehensive baseline information on the Antarctic marine biodiversity as a sound benchmark against which future change can reliably be assessed. CAML was initiated in 2005 as the regional Antarctic project of the worldwide programme Census of Marine Life (2000-2010) and was the most important biology project of the International Polar Year 2007-2009.

The SCAR Marine Biodiversity Information Network (SCAR-MarBIN)

In close connection with CAML, SCAR-MarBIN (www.scarmarbin.be, integrated into www.biodiversity.aq) compiled and managed the historic, current and new information (i.a. generated by CAML) on Antarctic marine biodiversity by establishing and supporting a distributed system of interoperable databases, forming the Antarctic regional node of the Ocean Biogeographic Information System (OBIS, www.ibis.org), under the aegis of SCAR (Scientific Committee on Antarctic Research, www.scar.org). SCAR-MarBIN established a comprehensive register of Antarctic marine species and, with biodiversity.aq provided free access to more than 2.9 million Antarctic georeferenced biodiversity data, which allowed more than 60 million downloads.

The scope of the Biogeographic Atlas of the Southern Ocean is to present a concise synopsis of the present state of knowledge of the distributional patterns of the major benthic and pelagic taxa and of the key communities, in the light of biotic and abiotic factors operating within an evolutionary framework. Each chapter has been written by the most pertinent experts in their field, relying on vastly improved occurrence datasets from recent decades, as well as on new insights provided by molecular and phylogeographic approaches, and new methods of analysis, visualisation, modelling and prediction of biogeographic distributions.

A dynamic online version of the Biogeographic Atlas will be hosted on www.biodiversity.aq.
